(54) Title: CLASSIFICATION, DIAGNOSIS AND PROGNOSIS OF ACUTE MYELOID LEUKEMIA BY GENE EXPRESSION PROFILING

(57) Abstract: The present invention relates to methods of genetic analysis for the classification, diagnosis and prognosis of acute myeloid leukemia (AML). The invention provides a method for producing a classification scheme for AML comprising the steps of a) providing a plurality of reference samples, said reference samples comprising cell samples from a plurality of reference subjects affected by AML; b) providing reference profiles by establishing a gene expression profile for each of said reference samples individually; c) clustering said individual reference profiles according to similarity, and d) assigning an AML class to each cluster. The invention further relates to a method for classifying the AML of an AML affected subject, to a method for diagnosing AML in a subject, and to a method of determining the prognosis for an AML affected subject.

WO 2005/080601 A2

Title: Classification, diagnosis and prognosis of acute myeloid leukemia by gene expression profiling.

TECHNICAL FIELD

The present invention is in the field of medicine. The invention relates in particular to methods of genetic analysis for the classification, diagnosis and prognosis of acute myeloid leukemia. Also, the invention relates to nucleic acid expression profiles as obtained from cells of AML patients, which profiles by similarity group into a plurality of distinct and defined clusters that characterize different classes of AML. The invention relates to the use of such expression profiles and compositions in diagnosis and therapy of AML and specifically in the prediction of prognostically important AML classes.

The invention further relates to methods for the diagnosis of AML and for the determination of the prognosis of a subject affected by AML and to kits of parts comprising sets of nucleic acid probes suitable for performing methods of the invention either by means of genomics or proteomics.

15

BACKGROUND OF THE INVENTION

Acute myeloid leukemia (AML) is a collection of neoplasms with heterogeneous pathophysiology, genetics and prognosis. Based on cytogenetics and molecular analysis, AML patients are presently classified into groups or subsets of AML with markedly contrasting prognosis. For instance, the genetic translocations inv(16), t(8;21) and t(15;17) characterize AML with a relatively favourable prognosis, whereas the cytogenetically bad-risk leukemia's include patients with abnormalities involving 11q23, loss of 5(q) or 7(q), t(6;9) and t(9;22) (Löwenberg *et al.*, 1999).

25

The most common molecular abnormality in AML is the internal tandem duplication (ITD) in the *fms*-like tyrosine kinase-3 gene (*FLT3*), a hematopoietic growth factor receptor (Levis & Small, 2003). *FLT3* ITD

mutations confer a bad prognosis to AML patients (Levis & Small, 2003). AML patients with mutations in the transcription factor cEBP α have been associated with good outcome (Preudhomme *et al.*, 2002; van Waalwijk van Doorn-Khosrovani *et al.*, 2003), while elevated expression of the transcription factor EVI1 predicts for notoriously poor survival (van Waalwijk van Doorn-Khosrovani *et al.*, 2003). These examples of novel molecular prognostic markers underscore the importance of an extension of molecular analyses in AML.

Approximately thirty percent of all patients with acute myeloid leukemia (AML) are currently classified based on specific abnormal karyotypes in groups with either good or bad prognosis. The remaining seventy percent of patients, however, are not classifiable because of the lack of cytogenetic markers.

One of the aims of the present invention is to provide more accurate risk assessment tools for the diagnosis of AML. It is another aim to classify AML patients in which specific abnormal karyotypes have not been found and to distinguish these groups not only from the molecularly well-defined AML classes, but also to define prognostic subgroups within these unclassified AML types. The presence of additional prognostic classes in AML, not recognizable with currently available methods, may provide important insights into their pathophysiology. Therefore, it is an aim of the present invention to provide a more complete way of prognostication to patients with AML.

SUMMARY OF THE INVENTION

The present invention is based on the discovery that unique correlations within gene expression profiles and also with cytogenetic aberrations can be recognized with high accuracy within a representative cohort of AML patients. It has for instance been found that gene expression profiles obtained from a large number of AML patients can be clustered according to similarity. This enables the recognition of distinct classes of AML

with similar expression profiles characterising such a class. It was thus found that AML could be classified into distinct subclasses, each subclass being characterised by a specific clustering of gene expression profiles. Further it was found that truly discriminative genes for most of these classes or clusters could be identified, a cluster for instance being characterized therein that the expression of multiple genes is up-regulated or down-regulated in that cluster whereas their expression in another cluster is unaffected.

Based on these findings, the present invention now provides in a first aspect a method for producing a classification scheme for AML comprising the steps of:

- a) providing a plurality of reference samples, said reference samples comprising cell samples from a plurality of reference subjects affected by AML;
- b) providing reference profiles by establishing a gene expression profile for each of said reference samples individually;
- c) clustering said individual reference profiles according to similarity, and
- d) assigning an AML class to each cluster.

In a preferred embodiment of such a method, the clustering of reference profiles is performed based on the information of genes that are differentially-expressed between profiles, and in an even more preferred embodiment of such a method, the clustering of said reference profiles is performed on the basis of the information of the genes of table 1, still more preferably of the genes of table 2, which tables are provided hereinbelow. In a further aspect, the present invention provides a method for classifying the AML of an AML affected subject, comprising the steps of:

- a) providing a classification scheme for AML by producing such a scheme according to the method of any one of claims 1-3;
- b) providing a subject profile by establishing a gene expression profile for said subject;
- c) clustering the subject profile together with the reference profiles;

- d) determining in said scheme the clustered position of said subject profile among the reference profiles, and
- e) assigning to said AML of said subject the AML class that corresponds to said clustered position in case said subject profile is within any cluster of reference profiles, or assigning to said AML of said subject a new AML class.

In yet a further aspect, the present invention provides a method for diagnosing AML in an AML affected subject comprising:

- a) producing a classification scheme for AML according to a method of the invention;
- b) defining cluster-specific genes for each cluster by selecting those genes of which the expression level characterizes the clustered position of the corresponding AML class among the various AML classes within said scheme;
- c) determining the level of expression of a sufficient number of said cluster-specific genes in an AML affected subject;
- d) establishing whether the level of expression of said cluster-specific genes in said subject shares sufficient similarity to the level of expression that characterizes an individual AML class to thereby determine the presence of AML corresponding to said class in said subject.

In one embodiment of such a method for diagnosing AML, said cluster-specific genes may comprise all genes comprised in said gene expression profile. In a preferred embodiment of such a method, said cluster-specific genes comprise a set of 1 to 3000 genes of the genes of table 1, more preferably 1 to 600 genes of the genes of table 1, still more preferably 1 to 50 genes of the genes of table 1. In an even more preferred embodiment said cluster-specific genes comprise a set of 1 to 600 genes of the genes of table 2, still more preferably 1 to 50 genes of the genes of table 2, and even more preferably 1 to 25 genes of the genes of table 2. Most preferred in such a

method is the use of the differentially-expressed genes as shown in Table 3 for the diagnosis of a specific AML class in a subject.

In yet another aspect, the present invention provides a method of determining the prognosis for an AML affected subject, said method

5 comprising the steps of:

- a) providing a classification scheme for AML by producing such a scheme according to a method of the invention;
- b) determining the prognosis for each AML class in said scheme based on clinical records for the AML subjects comprised in said class;
- 10 c) establishing the AML class of an AML affected subject by diagnosing and/or classifying AML in said subject according to a method of the invention, and
- d) assigning to said subject the prognosis corresponding to the established AML class of said AML affected subject.

15 The present invention further provides a classification scheme for AML, said scheme comprising a plurality of distinct AML classes that are differentiated on the basis of similarity clustering of gene expression profiles obtained from a plurality of reference subjects affected by AML.

Said classification scheme is for instance obtainable by a method of
20 the invention for producing such a scheme. Preferably, said classification scheme is obtained by a method involving K-means clustering of gene expression profiles based on, for instance, gene chip array-acquired values for hybridization intensities for each gene, such as for instance those obtainable by using an Affymetrix gene chip.

25 Analysis of gene expression profiles obtained by using such gene chips preferably involves log 2 transformation of all intensity values in order to detect subtle modulations between the various genes. For each gene the geometric mean (i.e. the mean expression value determined for all individual genes in all profiles to be analysed) is calculated. Deviation from this geometric
30 mean is termed differential expression. Genes that are expressed at values

allowing assignment of being differentially-expressed are used for hierarchical clustering. Subsequently the gene signatures (characteristic expression profiles) of all samples/patients are compared with each other by means of a Pearson correlation coefficient analysis showing the (pathway) resemblance within clinical distinct groups of the total patient population.

The present invention further provides genes that are modulated (up- and down-regulated) in AML compared to the geometric mean calculated from all patients. Such genes and the proteins they encode are useful for diagnostic and prognostic purposes, and may also be used as targets for screening therapeutic compounds that modulate AML, such as antibodies. The methods of detecting nucleic acids of the invention or their encoded proteins can be used for a number of purposes. Examples include early detection of AML, monitoring and early detection of relapse following treatment of AML, monitoring response to therapy of AML, determining prognosis of AML, directing therapy of AML, selecting patients for postoperative chemotherapy or radiation therapy, selecting therapy, determining tumor prognosis, treatment, or response to treatment, and early detection of precancerous condition. Other aspects of the invention will become apparent to the skilled artisan by the following description of the invention.

In one aspect, the present invention provides a method of detecting an AML-associated transcript in one or more cells from a patient, the method comprising contacting a biological sample from the patient with a polynucleotide, such as an oligonucleotide, that selectively hybridizes to a sequence at least 80% identical to a sequence of a gene as shown in Tables 1 or 2. In one embodiment, the polynucleotide selectively hybridizes to a sequence at least 95% identical to a sequence of a gene as shown in Tables 1 or 2. In another embodiment, the polynucleotide comprises a sequence of a gene as shown in Tables 1 or 2.

In one embodiment, the biological sample used in such methods of detection is a tissue sample. In another embodiment, the biological sample

comprises isolated nucleic acids, e.g., mRNA. In one embodiment, the polynucleotide is labeled, e.g., with a fluorescent label. In one embodiment, the polynucleotide is immobilized on a solid surface.

5

DESCRIPTION OF THE DRAWINGS

Figure 1 shows, in panel (A), a Correlation View of 286 AML patients. The Correlation Visualization tool displays pair-wise correlations between the samples. The patient samples in the visualization are colored by Pearson's correlation coefficient values with deeper colors indicating higher positive (red) or negative (blue) correlations, indicating similarity in the underlying pathway indicative for the subgroups reflecting the heterogeneity within the patient population. The scale bar indicates 100% correlation (red) towards 100% anti correlation (blue). In order to reveal correlation patterns, a matrix ordering method is applied to rearrange the samples. The ordering algorithm starts with the most correlated sample pair and, through an iterative process, sorts all the samples into correlated blocks. Each sample is joined to a block in an ordered manner so that a correlation trend is formed within a block with the most correlated samples at the centre. The blocks are then positioned along the diagonal of the plot in a similar ordered manner.

Panel (B) of Figure 1 shows an adapted Correlation View of 286 AML patients (right panel) and top40 genes defining the 16 individual clusters of patients (left panel). All 16 clusters identified on the basis of the Correlation View are indicated (1 to 16). FAB classification and karyotype based on cytogenetics are depicted in the columns along the original diagonal of the Correlation View (FAB M1-green, M2-purple, M3-orange, M4-yellow, M5-blue, M6-grey; karyotype: normal-green, inv(16)-yellow, t(8;21)-purple, t(15;17)-orange, 11q23 abnormalities-blue, other-grey). *FLT3* ITD, *FLT3* TKD, *N-RAS*, *K-RAS* and *cEBP α* mutations and *EVI1* overexpression are depicted in the same set of columns (red bar: positive and green bar: negative). The expression

levels of the top40 genes identified by Significance Analysis of Microarrays (SAM) analyses of each of the 16 clusters are visualized in the left panel. The scale bar indicates 4-fold upregulation (red) towards 4-fold downregulation (green) relative to the geometric mean of all samples.

5 Figure 2 shows the overall survival (panel A), event free survival (panel B) and relapse rate after CR (panel C) of AML patients in cluster #5 (M4/M5), cluster #9 (inv(16)), cluster #10 (*EVI1*/monosomy 7), cluster #12 (t(15;17)) and cluster #13 (t(8;21)), indicating that expression profiles in acute myeloid leukemia associate with diverse genetic aberrations and have
10 prognostic impact.

 Figure 3 provides a guideline on how to read the Omniviz Correlation View. The figure shows the Correlation View and FAB classification (right-hand edge of figure) of the cohort of 286 AML patients (2856 probe sets). A total of 16 distinct cluster can be identified on the right
15 edge of the figure. X-axis and Y-axis show the regions of the various clusters 1-16 from top to bottom and from left to right, respectively. An exemplary correlation between cluster #5 and #16 is indicated by rectangle. Both clusters predominantly consist of AML-M5 (not visible) and correlate. However, they do form separate clusters. Anti-correlation for instance between cluster 5 and
20 cluster #13, which merely contains AML-M2, is indicated by the dashed rectangle. Correlation and anti-correlation between every individual (sub)cluster can be extracted from the Correlation View and (sub)clusters can subsequently be assigned, e.g., cluster #6, #7 and #8 (dotted lines). FAB: M0-
25 bright green, M1-green, M2-pink, M3-orange, M4-purple, M5-turquoise, M6-yellow (with number).

 Figures 4-10 provide supporting results of the Pearson's correlation coefficient analyses using Omniviz with different probe subsets. In the Correlation View all 286 patients are plotted against all 286 AML patients. FAB classification and karyotype based on cytogenetics are depicted in the
30 columns along the original diagonal (left-hand edge) of the Correlation View

(FAB M0-red, M1-green, M2-purple, M3-orange, M4-yellow, M5-blue, M6-grey; karyotype: normal-green, inv(16)-yellow, t(8;21)-purple, t(15;17)-orange, 11q23 abnormalities-blue, 7(q) abnormalities-red, +8-pink, complex-black, other-grey). *FLT3* ITD, *FLT3* TKD, N-RAS, K-RAS and *cEBP α mutations and *EVI1**

5 overexpression are depicted in the same set of columns (red bar: positive and green bar: negative). Figure 4: 147 probe; Figure 5: 293 probe sets; Figure 6: 569 probe sets; Figure 7: 984 probe sets; Figure 8: 1692 probe sets; Figure 9: 2856 probe sets; Figure 10: 5071 probe sets.

Figure 11 shows the Southern blot analyses AML patients with
10 cryptic inv(16). Southern blot analyses was carried out with a myosine heavy chain 11 specific probe (NT 010393, 136753-137404 nt) on material of AML (WT, no inv(16)), AML with known inv(16) breakpoint (type A and E) and three patients that clustered with all known AML and inv(16) patients in the Correlation View (Figure 1).

15 Figure 12 shows the Expression of *MYH11* as determined by Affymetrix GeneChip analyses in 286 cases of AML and controls. Expression levels of *MYH11* were high in AML patients and inv(16), whereas low levels were detected in the other AML patients, CD34-positive cells and normal bone marrow.

20 Figure 13 shows a snapshot of Correlation View showing the AML-M3 t(15;17) patients. FAB M2-purple, M3-orange, M4-yellow. Karyotype: normal-green, t(15;17)-orange, other-grey. The AML-M3 t(15;17) patients are divided into two groups, i.e., low white blood cell count (WBC) and *FLT3* ITD negative (green bar) versus high WBC/ *FLT3* ITD positive (red bar). Karyotype
25 is based on cytogenetics and WBC is depicted as 10 (cells/l).

Figure 14 shows the Expression of *ETO* as determined by Affymetrix GeneChip analyses in 286 cases of AML and controls. Expression levels of *ETO* were high in AML patients and t(8;21), whereas low levels were detected in the other AML patients, CD34-positive cells and normal bone marrow.

DETAILED DESCRIPTION OF THE INVENTION

The term "classifying" is used in its art-recognized meaning and thus refers to arranging or ordering items, *i.c.* gene expression profiles, by classes or categories or dividing them into logically hierarchical classes, subclasses, and sub-subclasses based on the characteristics they have in common and/or that distinguish them. In particular "classifying" refers to assigning, to a class or kind, an unclassified item. A "class" then being a grouping of items, based on one or more characteristics, attributes, properties, qualities, effects, parameters, etc., which they have in common, for the purpose of classifying them according to an established system or scheme.

The term "classification scheme" is used in its art-recognized meaning and thus refers to a list of classes arranged according to a set of pre-established principles, for the purpose of organizing items in a collection or into groups based on their similarities and differences.

The term "clustering" refers to the activity of collecting, assembling and/or uniting into a cluster or clusters items with the same or similar elements, a "cluster" referring to a group or number of the same or similar items, *i.c.* gene expression profiles, gathered or occurring closely together based on similarity of characteristics. "Clustered" indicates an item has been subjected to clustering.

The term "clustered position" refers to the location of an individual item, *i.c.* a gene expression profile, in amongst a number of clusters, said location being determined by clustering said item with at least a number of items from known clusters.

The process of clustering used in a method of to the present invention may be any mathematical process known to compare items for similarity in characteristics, attributes, properties, qualities, effects, parameters, etc.. Statistical analysis, such as for instance multivariate analysis, or other methods of analysis may be used. Preferably methods of analysis such as self-organising maps, hierarchical clustering,

multidimensional scaling, principle component analysis, supervised learning, k-nearest neighbours, support vector machines, discriminant analyse, partial least square methods and/or Pearson's correlation coefficient analysis are used. In another preferred embodiment of a method of the present invention

- 5 Pearson's correlation coefficient analysis, significance analysis of microarrays (SAM) and/or prediction analysis of microarrays (PAM) are used to cluster gene expression profiles according to similarity. A highly preferred method of clustering comprises similarity clustering of gene expression profiles wherein the expression level of differentially-expressed genes, having markedly lower
10 or higher expression than the geometric mean expression level determined for all genes in all profiles to be clustered, is $\log(2)$ transformed, and wherein the transformed expression levels of all differentially-expressed genes in all profiles to be clustered is clustered by using K-means. A numerical query may then be used to select a subset of genes used in the process of hierarchical
15 clustering (Eisen et al., 1998), thus, numerical queries may be run to select differentially expressed genes relative to the calculated geometric mean to select a smaller group of genes for hierarchical clustering.

- Unsupervised sample clustering using genes obtained by numerical or threshold filtering is used to identify discrete clusters of samples as well as
20 the gene-signatures associated with these clusters. The term gene signatures is used herein to refer to the set of genes that define the discrete position of the cluster apart from all other clusters, and includes cluster-specific genes. A numerical or threshold filtering is used to select genes for the analysis that are most likely of diagnostic relevance. Hierarchical clustering allows for
25 visualization of large variation in gene expression across samples or present in most samples, and these genes could be used for unsupervised clustering so that clustering results are not affected by the noise from absent or non-changed genes.

- Thus, while, K-means clustering may be performed on all genes, the
30 Pearson correlation is preferably calculated based on a subset of genes and

patients. Generally speaking the larger the threshold for accepting a deviation or change from the geometric mean, the smaller the number of genes that is selected by this filtering procedure. Different cut-off or threshold values were used to prepare lists with different numbers of genes. The higher the number
5 of genes selected and included on such lists, the more noise is generally encountered within the dataset, because there will be a relatively large contribution of non- leukemia pathway related genes in such lists. The filtering and selection procedure is preferably optimized such that the analysis is performed on as much genes as possible, while minimizing the noise.

10 All genes with changed expression values higher than or equal to 1.5 times the $\log(2)$ transformed expression values and genes with changed expression values lower than or equal to -1.5 times the $\log(2)$ transformed expression values are selected for hierarchical clustering.

The subset of genes showing a markedly higher or lower expression
15 than the geometric mean may for instance be a value that is more than 1.5 times the geometric mean value, preferably more than 2 times the geometric mean value, even more preferably more than 3 times the geometric mean value. Likewise, a markedly lower expression than the geometric mean expression level may for instance be a value that is less than 0.8 times the
20 geometric mean value, preferably less than 0.6 times the geometric mean value, more preferably less than 0.3 times the geometric mean value. The same selection of genes that is used for the hierarchical clustering, is used for clustering of the patients by Pearson correlation coefficient analysis.

Gene expression profiling has previously been demonstrated to be
25 useful in distinguishing myeloid from lymphoid malignancies as well as subclasses within these diseases (Alizadeh *et al.*, 2000; Armstrong *et al.*, 2002; Debernardi *et al.*, 2003; Ross *et al.*, 2003; Yeoh; Schoch *et al.*, 2002; Golub *et al.*, 1999), but it was hitherto unknown whether suitable distinctions on the basis of gene expression alone could be made between various types of AML,

let alone whether such distinctions could bear any relevance to prognosis of the disease.

The present invention now provides several methods to accurately identify known as well as newly discovered diagnostically, prognostically and therapeutically relevant subgroups of acute myeloid leukemia (AML), herein
5 below also addressed as AML classes, as well as methods that can predict which approaches in treatment are likely to be effective. The basis of these methods resides in the measurement of (AML-specific) gene expression in AML-affected subjects. The methods and compositions of the invention thus
10 provide tools useful in choosing a therapy for AML patients, including methods for assigning an AML patient to an AML class or AML cluster, methods of choosing a therapy for an AML patient, methods of determining the efficacy of a therapy in an AML patient, and methods of determining the prognosis for an AML patient.

15 The methods of the invention comprise in various aspects the steps of establishing a gene expression profile of subject samples, for instance of reference subjects affected by AML or of a subject diagnosed or classified for AML. The expression profiles of the present invention are generated from samples from subjects affected by AML, including subjects having AML,
20 subjects suspected of having AML, subjects having a propensity to develop AML, or subjects who have previously had AML, or subjects undergoing therapy for AML. The samples from the subject used to generate the expression profiles of the present invention can be derived from a variety of sources including, but not limited to, single cells, a collection of cells, tissue,
25 cell culture, bone marrow, blood, or other bodily fluids. The tissue or cell source may include a tissue biopsy sample, a cell sorted population, cell culture, or a single cell. Sources for the sample of the present invention include cells from peripheral blood or bone marrow, such as blast cells from peripheral blood or bone marrow.

In selecting a sample, the percentage of the sample that constitutes cells having differential gene expression in AML classes should be considered. Samples may comprise at least 20%, at least 30%, at least 40%, at least 50%, at least 55%, at least 60%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, or at least 95% cells having differential expression in AML classes, with a preference for samples having a high percentage of such cells. In some embodiments, these cells are blast cells, such as leukemic cells. The percentage of a sample that constitutes blast cells may be determined by methods well known in the art; see, for example, the methods described in WO 03/083140.

"Gene expression profiling" or "expression profiling" is used herein in its art-recognized meaning and refers to a method for measuring the transcriptional state (mRNA) or the translational state (protein) of a plurality of genes in a cell. Depending on the method used, such measurements may involve the genome-wide assessment of gene expression, but also the measurement of the expression level of selected genes, resulting in the establishment of a "gene expression profile" or "expression profile", which terms are used in that meaning hereinbelow. As used herein, an "expression profile" comprises one or more values corresponding to a measurement of the relative abundance of a gene expression product. Such values may include measurements of RNA levels or protein abundance. Thus, the expression profile can comprise values representing the measurement of the transcriptional state or the translational state of the gene. In relation thereto, reference is made to U.S. Pat. Nos. 6,040,138, 5,800,992, 6,020,135, 6,344,316, and 6,033,860.

The transcriptional state of a sample includes the identities and relative abundance of the RNA species, especially mRNAs present in the sample. Preferably, a substantial fraction of all constituent RNA species in the sample are measured, but at least a sufficient fraction to characterize the transcriptional state of the sample is measured. The transcriptional state can

be conveniently determined by measuring transcript abundance by any of several existing gene expression technologies.

Translational state includes the identities and relative abundance of the constituent protein species in the sample. As is known to those of skill in the art, the transcriptional state and translational state are related.

Each value in the expression profiles as determined and embodied in the present invention is a measurement representing the absolute or the relative expression level of a differentially-expressed gene. The expression levels of these genes may be determined by any method known in the art for assessing the expression level of an RNA or protein molecule in a sample. For example, expression levels of RNA may be monitored using a membrane blot (such as used in hybridization analysis such as Northern, Southern, dot, and the like), or microwells, sample tubes, gels, beads or fibers (or any solid support comprising bound nucleic acids). See U.S. Patent Nos. 5,770,722, 5,874,219, 5,744,305, 5,677,195 and 5,445,934, to which explicit reference is made. The gene expression monitoring system may also comprise nucleic acid probes in solution.

In one embodiment of the invention, microarrays are used to measure the values to be included in the expression profiles. Microarrays are particularly well suited for this purpose because of the reproducibility between different experiments. DNA microarrays provide one method for the simultaneous measurement of the expression levels of large numbers of genes. Each array consists of a reproducible pattern of capture probes attached to a solid support. Labeled RNA or DNA is hybridized to complementary probes on the array and then detected by laser scanning. Hybridization intensities for each probe on the array are determined and converted to a quantitative value representing relative gene expression levels. See, the Experimental section. See also, U.S. Pat. Nos. 6,040,138, 5,800,992 and 6,020,135, 6,033,860, and 6,344,316, to which explicit reference is made. High-density oligonucleotide

arrays are particularly useful for determining the gene expression profile for a large number of RNA's in a sample.

In one approach, total mRNA isolated from the sample is converted to labeled cRNA and then hybridized to an oligonucleotide array. Each sample is hybridized to a separate array. Relative transcript levels are calculated by reference to appropriate controls present on the array and in the sample. See, for example, the Experimental section.

In another embodiment, the values in the expression profile are obtained by measuring the abundance of the protein products of the differentially-expressed genes. The abundance of these protein products can be determined, for example, using antibodies specific for the protein products of the differentially-expressed genes. The term "antibody" as used herein refers to an immunoglobulin molecule or immunologically active portion thereof, i.e., an antigen-binding portion. Examples of immunologically active portions of immunoglobulin molecules include F(ab) and F(ab')₂ fragments which can be generated by treating the antibody with an enzyme such as pepsin. The antibody can be a polyclonal, monoclonal, recombinant, e.g., a chimeric or humanized, fully human, non-human, e.g., murine, or single chain antibody. In a preferred embodiment it has effector function and can fix complement. The antibody can be coupled to a toxin or imaging agent. A full-length protein product from a differentially-expressed gene, or an antigenic peptide fragment of the protein product can be used as an immunogen. Preferred epitopes encompassed by the antigenic peptide are regions of the protein product of the differentially-expressed gene that are located on the surface of the protein, e.g., hydrophilic regions, as well as regions with high antigenicity. The antibody can be used to detect the protein product of the differentially-expressed gene in order to evaluate the abundance and pattern of expression of the protein. These antibodies can also be used diagnostically to monitor protein levels in tissue as part of a clinical testing procedure, e.g., to, for example, determine the efficacy of a given therapy. Detection can be facilitated

by coupling (i.e., physically linking) the antibody to a detectable substance (i.e., antibody labeling). Examples of detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials, bioluminescent materials, and radioactive materials. Examples of suitable enzymes include horseradish peroxidase, alkaline phosphatase, (3-
5 galactosidase, or acetylcholinesterase; examples of suitable prosthetic group complexes include streptavidin/biotin and avidin/biotin; examples of suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride
10 or phycoerythrin; an example of a luminescent material includes luminol; examples of bioluminescent materials include luciferase, luciferin, and aequorin, and examples of suitable radioactive material include ^{125}I , ^{131}I , ^{35}S or ^3H .

Once the values comprised in the subject expression profile and the
15 reference expression profile or expression profiles are established, the subject profile is compared to the reference profile to determine whether the subject expression profile is sufficiently similar to the reference profile. Alternatively, the subject expression profile is compared to a plurality of reference expression profiles to select the reference expression profile that is most similar to the
20 subject expression profile. Any method known in the art for comparing two or more data sets to detect similarity between them may be used to compare the subject expression profile to the reference expression profiles. In some embodiments, the subject expression profile and the reference profile are compared using a supervised learning algorithm such as the support vector
25 machine (SVM) algorithm, prediction by collective likelihood of emerging patterns (PCL) algorithm, the k-nearest neighbour algorithm, or the Artificial Neural Network algorithm. To determine whether a subject expression profile shows "statistically significant similarity" or "sufficient similarity" to a reference profile, statistical tests may be performed to determine whether the
30 similarity between the subject expression profile and the reference expression

profile is likely to have been achieved by a random event. Any statistical test that can calculate the likelihood that the similarity between the subject expression profile and the reference profile results from a random event can be used. The accuracy of assigning a subject to an AML class based on similarity
5 between differentially-expressed genes is affected largely by the heterogeneity within the patient population, as is reflected by the deviation from the geometric mean. Therefore, when more accurate diagnoses are required, the stringency in evaluating the similarity between the subject and the reference profile should be increased by changing the numerical query.

10 The method used for comparing a subject expression profile to one or more reference profiles is preferably carried out by re-running the subsequent analyses in a (n+1) modus by performing clustering methods as described herein. Also, in order to identify the AML class reference profile that is most similar to the subject expression profile, as performed in the methods for
15 establishing the AML class of an AML affected subject, *i.e.* by diagnosing AML in a subject or by classifying the AML in a subject, profiles are clustered according to similarity and it is determined whether the subject profile corresponds to a known class of reference profiles. In assigning a subject AML to a specific AML class for instance, this method is used wherein the clustered
20 position of the subject profile, obtained after performing the clustering analysis of the present invention, is compared to any known AML class. If the clustered position of the subject profile is within a cluster of reference profiles, *i.e.* forms a cluster therewith after performing the similarity clustering method, it is said that the AML of the subject corresponds to the AML class of reference profiles.
25 If a subject profile is not within a cluster of reference profiles, *i.e.* does not form a cluster therewith after performing the similarity clustering method, then a new AML class may be assigned to that subject profile, one of such classes being subjects not having AML.

 In some embodiments of the present invention, the expression
30 profiles comprise values representing the expression levels of genes that are

differentially-expressed in AML classes. The term "differentially-expressed" as used herein means that the measured expression level of a particular gene in the expression profile of one subject differs at least n-fold from the geometric mean calculated from all patient profiles. The expression level may be also be
5 up-regulated or down-regulated in a sample from a subject having a particular form of AML in comparison with a sample from a subject having a different form of AML. For example, in one embodiment, the differentially-expressed genes of the present invention may be expressed at different levels in different AML classes. Examples of genes that are differentially-expressed in the
10 various AML classes are shown in Tables 1 and 2.

It should be noted that many genes will occur, of which the measured expression level differs at least n-fold from the geometric mean expression level for that gene of all reference profiles. This may for instance be due to the different physiological state of the measured cells, to biological
15 variation or to the presence of other diseased states. Therefore, the presence of a differentially-expressed gene is not necessarily informative for determining the presence of different AML classes, nor is every differentially-expressed gene suitable for performing diagnostic tests. Moreover, a cluster-specific differential gene expression, as defined herein, is most likely to be informative
20 only in a test among subjects having AML. Therefore, a diagnostic test performed by using cluster-specific gene detection should preferably be performed on a subject in which the presence of AML is confirmed. This confirmation may for instance be obtained by performing the method for classifying an AML in an AML-affected subject according to the present
25 invention, or by any other test.

The present invention provides groups of genes that are differentially-expressed in diagnostic AML samples of patients in different AML classes. Some of these genes were identified based on gene expression levels for 13,000 probes in 286 AML samples. Values representing the
30 expression levels of the nucleic acid molecules detected by the probes were

analyzed as described in the Experimental section using Omniviz, SAM and PAM analysis tools. Omniviz software was used to perform all clustering steps such as K-means, Hierarchical and Pearson correlation tests. SAM was used specifically to identify the genes underlying the clinically relevant groups identified in the Pearson correlation analysis. PAM is used to decide the minimum number of genes necessary to diagnose all individual patients within the given groups of the Pearson correlation.

In short, expression profiling was carried out on AML blasts from 286 *de novo* AML patients. Unsupervised clustering was used to identify novel (sub)groups within the Pearson correlation following the hierarchical clustering. The Pearson correlation test resulted in the identification of 16 groups or classes of AML patients with distinct molecular signatures. The hierarchical clustering and Pearson correlation allow the detection of the genetic heterogeneity (16 clusters). This may provide for a mechanistic signature of AML. After running the SAM and PAM analysis the diagnostic gene-signatures (incl. cluster-specific genes) were obtained.

While several of the molecularly assigned classes correspond to the well-defined AML subgroups with favourable cytogenetics, such as the well recognised genetic lesions *AML1/ETO*, *PML/RAR α* and *CBF β /MYH11*, we identified several additional distinct classes of patients that were not identified as distinct classes of AML before. For instance, new identified AML clusters comprised genetic lesions such as *CEBP α* mutations, or *FLT3* ITD mutations, or 11q23 aberrations, indicating that these cytogenetic markers alone are not sufficient to determine the prognosis of an AML patient or the most optimal intervention strategy (drug treatment).

Whereas the well-defined AML subgroups *AML1/ETO*, *PML/RAR α* and *CBF β /MYH11*, could be identified based on measurement of the expression level of only one or two genes in a cell sample, many of the newly discovered AML classes were defined on the basis of differential expression of a plurality of genes. Genes that define an AML class are hereinafter also

termed cluster-specific genes or signature genes. Prediction Analysis of
Microarrays (PAM) was applied to determine the minimal gene sets that
predict these prognostically important clusters with high accuracy. In one of
the novel clusters half of the AML patients had unfavourable markers, such as
5 elevated expression of *EVII* and/or loss of chromosome 7(q). Interestingly,
more then 90 percent of patients in this cluster (cluster no. 10, see Example)
responded poorly to therapy. The fact that a distinct gene expression signature
defines this class of AML patients, suggests the existence of a currently
unknown gene- or pathway defect that corresponds with poor treatment
10 outcome.

The present invention thus provides a method of classifying AML.
Using this method, a total of 286 AML samples analysed on a DNA microarray
consisting of 22283 probe sets, representing approximately 13,000 genes could
be classified into at least 16 distinct clusters. These 16 distinct clusters of AML
15 patients were assigned on the basis of strong correlation between their
individual differential expression profiles for 2856 probe sets (Table 1; Figure
1). The methods used to analyze the expression level values to identify
differentially-expressed genes were employed such that optimal results in
clustering, *i.e.* unsupervised ordering, were obtained. This then resulting in
20 the definition of the 16 clusters of reference profiles based on molecular
signature. The genes that defined the position or clustering of these 16
individual clusters could be determined and the minimal sets of genes required
to accurately predict the prognostically important AML classes corresponding
to these clusters could be derived. It should be understood that the method for
25 classifying AML according to the present invention may result in a distinct
clustering pattern and therefore in a different classification scheme when
other (numbers of) subjects are used as reference, or when other types of
oligonucleotide microarrays for establishing gene expression profiles are used.

The present invention thus provides a comprehensive classification
30 of AML covering various previously identified genetically defined classes.

Further analysis of classes by prediction analysis of microarrays (PAM) to determine the minimum number of genes that defined or predicted these prognostically important classes resulted in the establishment of cluster-specific genes or signature genes. The presence of distinct gene expression
5 profiles defining the novel classes suggests the presence of yet unknown common gene defects or pathway defects among AML cases in those classes. Several classes could be distinguished on the basis of the expression level of a single gene, whereas others could only be distinguished on the basis of 20 or more differentially-expressed genes (Table 3).

10 The methods of the present invention comprise in some aspects the step of defining cluster-specific genes by selecting those genes of which the expression level characterizes the clustered position of the corresponding AML class among the various AML classes within a classification scheme of the present invention. Such cluster-specific genes are selected preferably on the
15 basis of PAM analysis. This method of selection comprises the following.

PAM, or partition round medoids, is one of the k-medoids methods. Different from usual k-means approach, it also accepts a dissimilarity matrix, and it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared Euclidean distances. The PAM-algorithm is based on the
20 search for 'k' representative objects or medoids among the observations of the dataset, which should represent the structure of the data. After finding a set of 'k' medoids, 'k' clusters are constructed by assigning each observation to the nearest medoid. The goal is to find 'k' representative objects which minimize the sum of the dissimilarities of the observations to their closest representative
25 object. The distance metric to be used for calculating dissimilarities between observations are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. PAM calculates how many genes are necessary to identify all members (patients) belonging to a certain cluster.

The methods of the present invention comprise in some aspects the step of establishing whether the level of expression of cluster-specific genes in a subject shares sufficient similarity to the level of expression that is characteristic for an individual AML class. This step is necessary in determining the presence of that particular AML class in a subject under investigation, in which case the expression of that gene is used as a disease marker. Whether the level of expression of cluster-specific genes in a subject shares sufficient similarity to the level of expression of that particular gene in an individual AML class may for instance be determined by setting a threshold value.

The present invention also reveals genes with a high differential level of expression in specific AML classes compared the geometric mean of all reference subjects. These highly differentially-expressed genes are selected from the genes shown in Table 2. These genes and their expression products are useful as markers to detect the presence of AML in a patient. Antibodies or other reagents or tools may be used to detect the presence of these markers of AML.

The present invention also reveals gene expression profiles comprising values representing the expression levels of genes in the various identified AML classes. In a preferred embodiment, these expression profiles comprise the values representing the differential expression levels. Thus, in one embodiment the expression profiles of the invention comprise one or more values representing the expression level of a gene having differential expression in a defined AML class. Each expression profile contains a sufficient number of values such that the profile can be used to distinguish one AML class from another. In some embodiments, the expression profiles comprise only one value. For example, it can be determined whether a subject affected by AML is in the AML class defined by cluster # 9 (inv(16)) based only on the expression level of MYH11 201497_x_at (see Tables 2 and 31). Similarly, it can be determined whether a subject affected by AML is in the

AML class defined by cluster # 12 (t(15,17)) based only on the expression level of the cDNA of 2 genes FGF13 205110_s_at and HGF 210997_at and 210998_s_at (see Tables 2 and 34). In this case, the expression profile comprises two values corresponding to two differentially-expressed genes. In
5 other embodiments, the expression profile comprises more than one or two values corresponding to a differentially-expressed gene, for example at least 3 values, at least 4 values, at least 5 values, at least 6 values, at least 7 values, at least 8 values, at least 9 values, at least 10 values, at least 11 values, at
10 least 12 values, at least 13 values, at least 14 values, at least 15 values, at least 16 values, at least 17 values, at least 18 values, at least 19 values, at least 20 values, at least 22 values, at least 25 values, at least 27 values, at least 30 values, at least 35 values, at least 40 values, at least 45 values, at least 50 values, at least 75 values, at least 100 values, at least 125 values, at
15 least 150 values, at least 175 values, at least 200 values, at least 250 values, at least 300 values, at least 400 values, at least 500 values, at least 600 values, at least 700 values, at least 800 values, at least 900 values, at least 1000 values, at least 1200 values, at least 1500 values, or at least 2000 or more values.

It is recognized that the diagnostic accuracy of assigning a subject to an AML class will vary based on the number of values contained in the
20 expression profile. Generally, the number of values contained in the expression profile is selected such that the diagnostic accuracy is at least 85%, at least 87%, at least 90%, at least 91%, at least 92%, at least 93%, at least 94%, at least 95%, at least 96%, at least 97%, at least 98%, or at least 99%, as calculated using methods described elsewhere herein, with an obvious
25 preference for higher percentages of diagnostic accuracy.

It is recognized that the diagnostic accuracy of assigning a subject to an AML class will vary based on the strength of the correlation between the expression levels of the differentially-expressed genes within that specific AML class. When the values in the expression profiles represent the expression
30 levels of genes whose expression is strongly correlated with that specific AML

class, it may be possible to use fewer number of values (genes) in the expression profile and still obtain an acceptable level of diagnostic or prognostic accuracy.

The strength of the correlation between the expression level of a differentially-expressed gene and a specific AML class may be determined by a statistical test of significance. For example, the chi square test used to select genes in some embodiments of the present invention assigns a chi square value to each differentially-expressed gene, indicating the strength of the correlation of the expression of that gene to a specific AML class. Similarly, the T-statistics metric and the Wilkins' metric both provide a value or score indicative of the strength of the correlation between the expression of the gene and its specific AML class. These scores may be used to select the genes of which the expression levels have the greatest correlation with a particular AML class to increase the diagnostic or prognostic accuracy of the methods of the invention, or in order to reduce the number of values contained in the expression profile while maintaining the diagnostic or prognostic accuracy of the expression profile. Preferably, a database is kept wherein the expression profiles of reference subjects are collected and to which database new profiles can be added and clustered with the already existing profiles such as to provide the clustered position of said new profile among the already present reference profiles. Furthermore, the addition of new profiles to the database will improve the diagnostic and prognostic accuracy of the methods of the invention. Preferably, in a method of the present invention SAM or PAM analysis tools are used to determine the strength of such correlations.

The methods of the invention comprise the steps of providing an expression profile from a sample from a subject affected by AML and comparing this subject expression profile to one or more reference profiles that are associated with a particular AML class, a class with a known prognosis, or a class with a favourable response to therapy. By identifying the AML class reference profile that is most similar to the subject expression profile, e.g.

when their clustered positions fall together, the subject can be assigned to an AML class. The AML class assigned is that with which the reference profile(s) are associated. Similarly, the prognosis of a subject affected by AML can be predicted by determining whether the expression profile from the subject is

5 sufficiently similar to a reference profile associated with an established prognosis, such as a good prognosis or a bad prognosis. Whenever a subject's expression profile can be assigned to an established AML class, a preferred intervention strategy, or therapeutic treatment can then be proposed for said subject, and said subject can be treated according to said assigned strategy. As

10 a result, treatment of a subject with AML can be optimized according to the specific class of AML with which the subject is affected. For instance, the AML class belonging to cluster # 12, characterized by the presence of t(15,17), may be treated with retinoic acid. Within one class or cluster, further division may be made according to responders and non-responders to treatment or therapy.

15 Such divisions may provide for further detailed characterisation of AML subjects. In another embodiment, the subject expression profile is from a subject affected by AML who is undergoing a therapy to treat the AML. The subject expression profile is compared to one or more reference expression profiles to monitor the efficacy of the therapy.

20 In some embodiments, the assignment of a subject affected by AML to an AML class is used in a method of choosing a therapy for the subject affected by AML. A therapy, as used herein, refers to a course of treatment intended to reduce or eliminate the affects or symptoms of a disease, in this case AML. A therapy regime will typically comprise, but is not limited to, a

25 prescribed dosage of one or more drugs or hematopoietic stem cell transplantation. Therapies, ideally, will be beneficial and reduce the disease state but in many instances the effect of a therapy will have non-desirable effects as well.

In one aspect, the present invention provides a method of

30 determining the prognosis for an AML affected subject, said method

comprising the steps of providing a classification scheme for AML by producing such a scheme according to a method of the invention and determining the prognosis for each AML class in said scheme based on clinical records for the AML subjects comprised in said class. In order to predict the progression of the disease in a subject, one has to rely on clinical records. The present invention provides for the assignment of the various clinical data recorded with reference subjects affected by AML to the various AML classes as defined herein. This assignment preferably occurs in a database. This has the advantage that once a new subject is identified as belonging to a particular AML class, either by performing a specific AML diagnostic method of the invention using the cluster-specific genes as disease markers or by performing a method of classifying an AML in an AML affected subject according to the invention, then the prognosis that is assigned to that class may be assigned to that subject.

The present invention provides compositions that are useful in determining the gene expression profile for a subject affected by AML and selecting a reference profile that is similar to the subject expression profile. These compositions include arrays comprising a substrate having capture probes that can bind specifically to nucleic acid molecules that are differentially-expressed in AML classes. Also provided is a computer-readable medium having digitally encoded reference profiles useful in the methods of the claimed invention.

The present invention provides arrays comprising capture probes for detection of polynucleotides (transcriptional state) or for detection of proteins (translational state) in order to detect differentially-expressed genes of the invention. By "array" is intended a solid support or substrate with peptide or nucleic acid probes attached to said support or substrate. Arrays typically comprise a plurality of different nucleic acid or peptide capture probes that are coupled to a surface of a substrate in different, known locations. These arrays, also described as "microarrays" or colloquially "chips" have been generally

described in the art, and reference is made U.S. Patent. Nos. 5,143,854, 5,445,934, 5,744,305, 5,677,195, 6,040,193, 5,424,186, 6,329,143, and 6,309,831 and Fodor *et al.* (1991) *Science* 251:767-77. These arrays may generally be produced using mechanical synthesis methods or light directed synthesis methods which incorporate a combination of photolithographic methods and solid phase synthesis methods. Typically, "oligonucleotide microarrays" will be used for determining the transcriptional state, whereas "peptide microarrays" will be used for determining the translational state of a cell.

"Nucleic acid" or "oligonucleotide" or "polynucleotide" or grammatical equivalents used herein means at least two nucleotides covalently linked together. Oligonucleotides are typically from about 5, 6, 7, 8, 9, 10, 12, 15, 25, 30, 40, 50 or more nucleotides in length, up to about 100 nucleotides in length. Nucleic acids and polynucleotides are a polymers of any length, including longer lengths, e.g., 200, 300, 500, 1000, 2000, 3000, 5000, 7000, 10,000, etc. A nucleic acid of the present invention will generally contain phosphodiester bonds, although in some cases, nucleic acid analogs are included that may have alternate backbones, comprising, e.g., phosphoramidate, phosphorothioate, phosphorodithioate, or O-methylphosphoroamidite linkages (see Eckstein, *Oligonucleotides and Analogues: A Practical Approach*, Oxford University Press); and peptide nucleic acid backbones and linkages. Other analog nucleic acids include those with positive backbones; non-ionic backbones, and non-ribose backbones, including those described in U.S. Pat. Nos. 5,235,033 and 5,034,506, and Chapters 6 and 7, ASC Symposium Series 580, *Carbohydrate Modifications in Antisense Research*, Sanghui & Cook, eds. Nucleic acids containing one or more carbocyclic sugars are also included within one definition of nucleic acids. Modifications of the ribose-phosphate backbone may be done for a variety of reasons, e.g. to increase the stability and half-life of such molecules in physiological environments or as probes on a biochip. Mixtures of naturally occurring nucleic acids and analogs can be made; alternatively, mixtures of

different nucleic acid analogs, and mixtures of naturally occurring nucleic acids and analogs may be made.

Particularly preferred are peptide nucleic acids (PNA) which includes peptide nucleic acid analogs. These backbones are substantially non-ionic under neutral conditions, in contrast to the highly charged phosphodiester backbone of naturally occurring nucleic acids. This results in two advantages. First, the PNA backbone exhibits improved hybridization kinetics. PNAs have larger changes in the melting temperature (T_m) for mismatched versus perfectly matched basepairs. DNA and RNA typically exhibit a 2-4 °C drop in T_m for an internal mismatch. With the non-ionic PNA backbone, the drop is closer to 7-9°C. Similarly, due to their non-ionic nature, hybridization of the bases attached to these backbones is relatively insensitive to salt concentration. In addition, PNAs are not degraded by cellular enzymes, and thus can be more stable.

The nucleic acids may be single stranded or double stranded, as specified, or contain portions of both double stranded or single stranded sequence. As will be appreciated by those in the art, the depiction of a single strand also defines the sequence of the complementary strand; thus the sequences described herein also provide the complement of the sequence. The nucleic acid may be DNA, both genomic and cDNA, RNA or a hybrid, where the nucleic acid may contain combinations of deoxyribo- and ribo-nucleotides, and combinations of bases, including uracil, adenine, thymine, cytosine, guanine, inosine, xanthine hypoxanthine, isocytosine, isoguanine, etc.

"Transcript" typically refers to a naturally occurring RNA, e.g., a pre-mRNA, hnRNA, or mRNA. As used herein, the term "nucleoside" includes nucleotides and nucleoside and nucleotide analogs, and modified nucleosides such as amino modified nucleosides. In addition, "nucleoside" includes non-naturally occurring analog structures. Thus, e.g. the individual units of a peptide nucleic acid, each containing a base, are referred to herein as a nucleoside.

As used herein a "nucleic acid probe or oligonucleotide" is defined as a nucleic acid capable of binding to a target nucleic acid of complementary sequence through one or more types of chemical bonds, usually through complementary base pairing, usually through hydrogen bond formation. As used herein, a probe may include natural (i.e., A, G, C, or T) or modified bases (7-deazaguanosine, inosine, etc.). In addition, the bases in a probe may be joined by a linkage other than a phosphodiester bond, so long as it does not functionally interfere with hybridization. Thus, e.g., probes may be peptide nucleic acids in which the constituent bases are joined by peptide bonds rather than phosphodiester linkages. It will be understood by one of skill in the art that probes may bind target sequences lacking complete complementarity with the probe sequence depending upon the stringency of the hybridization conditions. The probes are preferably directly labeled such as with isotopes, chromophores, lumiphores, chromogens, or indirectly labeled such as with biotin to which a streptavidin complex may later bind or with enzymatic labels. By assaying for the hybridization of the probe to its target nucleic acid sequence, one can detect the presence or absence of the select sequence or subsequence. Diagnosis or prognosis may be based at the genomic level, or at the level of RNA or protein expression.

The skilled person is capable of designing oligonucleotide probes that can be used in diagnostic methods of the present invention. Preferably, such probes are immobilised on a solid surface as to form an oligonucleotide microarray of the invention. The oligonucleotide probes useful in methods of the present invention are capable of hybridizing under stringent conditions to AML-associated nucleic acids, such as to one or more of the genes selected from Table 1, preferably to one or more of the genes selected from Table 2, more preferably to one or more of the genes selected from Table 3.

Techniques for the synthesis of arrays using mechanical synthesis methods are described in, e.g., U.S. Patent No. 5,384,261, to which reference is made herein. Although a planar array surface is preferred, the array may be

fabricated on a surface of virtually any shape or even a multiplicity of surfaces. Arrays may be peptides or nucleic acids on beads, gels, polymeric surfaces, fibers such as fiber optics, glass or any other appropriate substrate, for the purpose of which reference is made to U.S. Pat. Nos. 5,770,358, 5,789,162, 5,708,153, 6,040,193 and 5,800,992. Arrays may be packaged in such a manner as to allow for diagnostics or other manipulation of an all-inclusive device. Reference is for example made to U.S. Pat. Nos. 5,856,174 and 5,922,591.

The arrays provided by the present invention comprise capture probes that can specifically bind a nucleic acid molecule that is differentially-expressed in AML classes. These arrays can be used to measure the expression levels of nucleic acid molecules to thereby create an expression profile for use in methods of determining the diagnosis and prognosis for AML patients, and for monitoring the efficacy of a therapy in these patients as described elsewhere herein.

In some embodiments, each capture probe in the array detects a nucleic acid molecule selected from the nucleic acid molecules designated in Tables 1 and 2. The designated nucleic acid molecules include those differentially-expressed in AML classes selected from cluster #1-cluster #16 as depicted in figure 1.

The arrays of the invention comprise a substrate having a plurality of addresses, where each address has a capture probe that can specifically bind a target nucleic acid molecule. The number of addresses on the substrate varies with the purpose for which the array is intended. The arrays may be low-density arrays or high-density arrays and may contain 4 or more, 8 or more, 12 or more, 16 or more, 20 or more, 24 or more, 32 or more, 48 or more, 64 or more, 72 or more, 80 or more, 96, or more addresses, or 192 or more, 288 or more, 384 or more, 768 or more, 1536 or more, 3072 or more, 6144 or more, 9216 or more, 12288 or more, 15360 or more, or 18432 or more addresses. In some embodiments, the substrate has no more than 12, 24, 48, 96, or 192, or

384 addresses, no more than 500, 600, 700, 800, or 900 addresses, or no more than 1000, 1200, 1600, 2400, or 3600 addresses.

The invention also provides a computer-readable medium comprising one or more digitally encoded expression profiles, where each profile has one or more values representing the expression of a gene that is differentially-expressed in an AML class. The preparation and use of such profiles is well within the reach of the skilled person (see e.g. WO 03/083140). In some embodiments, the digitally-encoded expression profiles are comprised in a database. See, for example, U.S. Patent No. 6,308,170.

The present invention also provides kits useful for diagnosing, treating, and monitoring the disease state in subjects affected by AML. These kits comprise an array and a computer readable medium. The array comprises a substrate having addresses, where each address has a capture probe that can specifically bind a nucleic acid molecule (by using an oligonucleotide array) or a peptide (by using a peptide array) that is differentially-expressed in at least one AML class. The results are converted into a computer-readable medium that has digitally-encoded expression profiles containing values representing the expression level of a nucleic acid molecule detected by the array.

By using the array described above, the amounts of various kinds of nucleic acid molecules contained in a nucleic acid sample can be simultaneously determined. In addition, there is an advantage such that the determination can be carried out even with a small amount of the nucleic acid sample. For instance, mRNA in the sample is labeled, or labeled cDNA is prepared by using mRNA as a template, and the labeled mRNA or cDNA is subjected to hybridization with the array, so that mRNAs being expressed in the sample are simultaneously detected, whereby their expression levels can be determined.

Genes each of which expression is altered due to AML can be found by determining expression levels of various genes in the AML affected cells

and classified into certain types as described above and comparing the expression levels with the expression level in a control tissue.

The method for determining the expression levels of genes is not particularly limited, and any of techniques for confirming alterations of the gene expressions mentioned above can be suitably used. Among all, the method using the array is especially preferable because the expressions of a large number of genes can be simultaneously determined. Suitable arrays are commercially available, e.g., from Affymetrix.

For instance, mRNA is prepared from blast cells, and then reverse transcription is carried out with the resulting mRNA as a template. During this process, labeled cDNA can be obtained by using, for instance, any suitable labeled primers or labeled nucleotides.

As to the labeling substance used for labeling, there can be used substances such as radioisotopes, fluorescent substances, chemiluminescent substances and substances with fluophor, and the like. For instance, the fluorescent substance includes Cy2, FluorX, Cy3, Cy3.5, Cy5, Cy5.5, Cy7, fluorescein isothiocyanate (FITC), Texas Red, Rhodamine and the like. In addition, it is desired that samples to be tested (cancer samples to be tested in the present selection method) and a sample to be used as a control are each labeled with different fluorescent substances, using two or more fluorescent substances, from the viewpoint of enabling simultaneous detection. Here, labeling of the samples is carried out by labeling mRNA in the samples, cDNA derived from the mRNA, or nucleic acids produced by transcription or amplification from cDNA.

Next, the hybridization is carried out between the above-mentioned labeled cDNA and the array to which a nucleic acid corresponding to a suitable gene or its fragment is immobilized. The hybridization may be performed according to any known processes under conditions that are appropriate for the array and the labeled cDNA to be used. For instance, the hybridization can

be performed under the conditions described in Molecular Cloning, A laboratory manual, 2nd ed., 9.52-9.55 (1989).

The hybridization between the nucleic acids derived from the samples and the array is carried out, under the above-mentioned hybridization
5 conditions. When much time is needed for the time period required for procedures from the collection of samples to the determination of expression levels of genes, the degradation of mRNA may take place due to actions of ribonuclease. In order to determine the difference in the gene expressions in the samples to be tested (i.e., cell or tissue samples of AML patients) and the
10 gene expressions in a control sample, it is preferable that the mRNA levels in both of these samples are adjusted using a standard gene with relatively little alterations in expressions.

Thereafter, by comparing the hybridization results of the samples to be tested with those of the control sample, genes exhibiting differential
15 expression levels in both samples can be detected. Concretely, a signal which is appropriate depending upon the method of labeling used is detected for the array which is subjected to hybridization with the nucleic acid sample labeled by the method as described above, whereby the expression levels in the samples to be tested can be compared with the expression level in the control
20 sample for each of the genes on the array.

The genes thus obtained which have a significant difference in signal intensities are genes each of which expression is altered specifically for certain AML classes.

The present invention also provides a computer-readable medium
25 comprising a plurality of digitally-encoded expression profiles wherein each profile of the plurality has a plurality of values, each value representing the expression of a gene that is differentially-expressed in at least one AML class. The invention also provides for the storage and retrieval of a collection of data relating to AML specific gene expression data of the present invention,
30 including sequences and expression levels in a computer data storage

apparatus, which can include magnetic disks, optical disks, magneto-optical disks, DRAM, SRAM, SGRAM, SDRAM, RDRAM, DDR RAM, magnetic bubble memory devices, and other data storage devices, including CPU registers and on-CPU data storage arrays. Typically, the data records are stored as a bit
5 pattern in an array of magnetic domains on a magnetizable medium or as an array of charge states or transistor gate states, such as an array of cells in a DRAM device (e.g., each cell comprised of a transistor and a charge storage area, which may be on the transistor).

For use in diagnostic, research, and therapeutic applications
10 suggested above, kits are also provided by the invention. In the diagnostic and research applications such kits may include any or all of the following: assay reagents, buffers, AML class-specific nucleic acids or antibodies, hybridization probes and/or primers, antisense polynucleotides, ribozymes, dominant
15 negative AML polypeptides or polynucleotides, small molecules inhibitors of AML-associated sequences, arrays, antibodies, Fab fragments, capture peptides etc. In addition, the kits may include instructional materials containing directions (i.e., protocols) for the practice of the methods of this invention. While the instructional materials typically comprise written or
20 printed materials, they are not limited to such. Any medium capable of storing such instructions and communicating them to an end user is contemplated by this invention. Such media include, but are not limited to electronic storage media (e.g., magnetic discs, tapes, cartridges, chips), optical media (e.g., CD ROM), and the like. Such media may include addresses to internet sites that
25 provide such instructional materials. One such internet site may provide a database of AML reference expression profiles useful for performing similarity clustering of a newly determine subject expression profiles with a large set of reference profiles of AML subjects comprised in said database. Preferably the database includes clinically relevant data such as patient prognosis, successful
30 methods of treatment and cytogenetic characteristics for the various AML classes in the database.

The invention encompasses for instance kits comprising an array of the invention and a computer-readable medium having digitally-encoded reference profiles with values representing the expression of nucleic acid molecules detected by the arrays. These kits are useful for assigning a subject
5 affected by AML to an AML class and for diagnosing AML in a subject.

The present invention also provides for kits for screening for modulators of AML-associated sequences. Such kits can be prepared from readily available materials and reagents. For example, such kits can comprise one or more of the following materials: an AML-associated polypeptide or
10 polynucleotide, reaction tubes, and instructions for testing AML-associated activity. Optionally the kit may comprise an array for detecting AML-associated genes, specifically cluster-defining genes according to the invention. A wide variety of kits and components can be prepared according to the present invention, depending upon the intended user of the kit and the
15 particular needs of the user.

Diagnosis would typically involve evaluation of a plurality of genes or products. The genes will be selected based on correlations with important parameters in disease which may be identified in historical or outcome data.

In a preferred embodiment a kit-of-parts according to the invention
20 comprises an oligonucleotide microarray according to the invention and means for comparing a gene expression profile determined by using said microarray with a database of AML reference expression profiles. The present invention also comprises kits of parts suitable for performing a method of the invention as well as the use of the various products of the invention, including databases,
25 microarrays, oligonucleotide probes and classification schemes in diagnostic or prognostic methods of the invention.

The methods and compositions of the invention may be used to screen test compounds to identify therapeutic compounds useful for the treatment of AML. In one embodiment, the test compounds are screened in a
30 sample comprising primary cells or a cell line representative of a particular

AML class. After treatment with the test compound, the expression levels in the sample of one or more of the differentially-expressed genes of the invention are measured using methods described elsewhere herein. Values representing the expression levels of the differentially-expressed genes are used to generate
5 a subject expression profile. This subject expression profile is then compared to a reference profile associated with the AML class represented by the sample to determine the similarity between the subject expression profile and the reference expression profile. Differences between the subject expression profile and the reference expression profile may be used to determine whether the test
10 compound has anti-leukemogenic activity.

The test compounds of the present invention can be obtained using any of the numerous approaches in combinatorial library methods known in the art, including: biological libraries; spatially addressable parallel solid phase or solution phase libraries; synthetic library methods requiring
15 deconvolution; the 'one-bead one-compound' library method; and synthetic library methods using affinity chromatography selection. The biological library approach is limited to polypeptide libraries, while the other four approaches are applicable to polypeptide, non-peptide oligomer or small molecule libraries of compounds (Lam (1997) *Anticancer Drug Res.* 12:145).

20 Examples of methods for the synthesis of molecular libraries can be found in the art, for example in DeWitt *et al.* (1993) *Proc. Natl. Acad. Sci. USA* 90:6909; Erb *et al.* (1994) *Proc. Natl. Acad. Sci. USA* 91:11422; Zuckermann *et al.* (1994) *J. Med. Chem.* 37:2678; Cho *et al.* (1993) *Science* 261:1303; Carell *et al.* (1994) *Angew. Chem. Int. Ed. Engl.* 33:2059; Carell *et al.* (1994) *Angew. Chem. Int. Ed. Engl.* 33:2061; and in Gallop *et al.* (1994) *J. Med. Chem.*
25 37:1233. Libraries of compounds may be presented in solution (*e.g.*, Houghten (1992) *Biotechniques* 13:412-421), or on beads (Lam (1991) *Nature* 354:82-84), chips (Fodor (1993) *Nature* 364:555-556), bacteria (U.S. Patent No. 5,223,409), spores (U.S. Patent No. 5,223,409), plasmids (Cull *et al.* (1992) *Proc. Natl.*
30 *Acad. Sci. USA* 89:1865-1869) or on phage (Scott and Smith (1990) *Science*

249:386-390; Devlin (1990) Science 249:404-406; Cwirla *et al.* (1990) Proc. Nad. Acad. Sci. U.S.A. 97:6378-6382; Felici (1991) J. Mol. Biol. 222:301-310).

Candidate compounds include, for example, 1) peptides such as soluble peptides, including Ig-tailed fusion peptides and members of random peptide libraries (see, e.g., Lam *et al.* (1991) Nature 354:82-84; Houghten *et al.* (1991) Nature 354:84-86) and combinatorial chemistry-derived molecular libraries made of D- and/or L- configuration amino acids; 2) phosphopeptides (e.g., members of random and partially degenerate, directed phosphopeptide libraries, see, e.g., Songyang *et al.* (1993) Cell 72:767-778); 3) antibodies (e.g., polyclonal, monoclonal, humanized, anti-idiotypic, chimeric, and single chain antibodies as well as Fab, F(ab')₂, Fab expression library fragments, and epitope binding fragments of antibodies); 4) small organic and inorganic molecules (e.g., molecules obtained from combinatorial and natural product libraries; 5) zinc analogs; 6) leukotriene A₄ and derivatives; 7) classical aminopeptidase inhibitors and derivatives of such inhibitors, such as bestatin and arphamenine A and B and derivatives; 8) and artificial peptide substrates and other substrates, such as those disclosed herein above and derivatives thereof.

The present invention discloses a number of genes that are differentially-expressed in AML classes. These differentially-expressed genes are shown in Tables 1 and 2. Because the expression of these genes is associated with AML risk factors, these genes may play a role in leukemogenesis. Accordingly, these genes and their gene products are potential therapeutic targets that are useful in methods of screening test compounds to identify therapeutic compounds for the treatment of AML. Genes that are common between a number of AML classes are preferred as targets for therapeutic treatment, since a broader working over the patient population can be expected. It is very likely that genes that are present in more than one AML class, as defined in the present invention, are involved in general processes underlying AML. Thus, the expression of these genes is

likely to be associated with AML risk factors and thus play a role in leukemogenesis. Genes that are present in several classes or clusters may thus define superclusters, which superclusters may define the processes that play an important role in leukemogenesis in general, and AML in particular.

5 The differentially-expressed genes of the invention may be used in cell-based screening assays involving recombinant host cells expressing the differentially-expressed gene product. The recombinant host cells are then screened to identify compounds that can activate the product of the differentially-expressed gene (*i.e.* agonists) or inactivate the product of the
10 differentially-expressed gene (*i.e.* antagonists).

Any of the leukemogenic functions mediated by the product of the differentially-expressed gene may be used as an endpoint in the screening assay for identifying therapeutic compounds for the treatment of AML. Such endpoint assays include assays for cell proliferation, assays for modulation of
15 the cell cycle, assays for the expression of markers indicative of AML, and assays for the expression level of genes differentially-expressed in AML classes as described above. Modulators of the activity of a product of a differentially-expressed gene identified according to these drug-screening assays provided above can be used to treat a subject with AML. These methods of treatment
20 include the steps of administering the modulators of the activity of a product of a differentially-expressed gene in a pharmaceutical composition as described herein, to a subject in need of such treatment.

The following examples are offered by way of illustration and not by way of limitation.

25

EXAMPLE 1

Methods Used

Patients and cell samples

5 Patients with a confirmed diagnosis of *de novo* AML were included in this study (Table 4). All patients were treated according to the HOVON (Dutch-Belgian Hematology-Oncology Co-operative group) protocols (<http://www.hovon.nl>). The treatment protocols have been described previously Rombouts *et al.*, 2001). Bone marrow or peripheral blood aspirations of AML
10 patients at diagnosis (n=286) and healthy volunteers (n=5) were taken after informed consent. Blasts and mononuclear cells were purified by Ficoll-Hypaque (Nygaard, Oslo, Norway) centrifugation and cryopreserved. CD34 positive cells of healthy volunteers (n=3) were sorted using the fluorescent activated cell sorter (FACS). According to cytological analysis the AML
15 samples contained 80-100% blast cells after thawing independent of the blast count at diagnosis.

RNA isolation and quality control

After thawing, cells were washed once with Hanks balanced salt
20 solution. High quality total RNA was extracted by lyses with guanidinium isothiocyanate followed by cesium chloride gradient purification (Chomczynski & Sacchi, 1987). RNA concentration, quality and purity were examined using the RNA 6000 Nano assay on the Agilent 2100 Bioanalyzer (Agilent, Amstelveen, The Netherlands). None of the samples showed RNA degradation
25 (28S/18S rRNA ratio ≥ 2) or DNA contamination.

Gene profiling and quality control

286 newly diagnosed cases of AML (Table 3) were analyzed by gene
profiling using the Affymetrix U133A GeneChip. The U133A GeneChips
30 contain 22283 probe sets representing approximately 13000 distinct genes.

Ten microgram of total RNA was used for the production of antisense biotinylated RNA. Single-stranded cDNA and double-stranded cDNA were synthesized according to the manufactures protocol (Invitrogen Life Technologies, Breda, The Netherlands) using the T7-(dT)24-primer (Genset Corp, Paris France). *In vitro* transcription was performed with biotin-11-CTP and biotin-16-UTP (Perkin Elmer, Hoofddorp, The Netherlands) and the MEGAScript T7 labeling kit (Ambion, Cambridgeshire, UK). Double-stranded cDNA and cRNA were purified and fragmented with the GeneChip Sample Cleanup Module (Affymetrix, Santa Clara, CA). Biotinylated RNA was subsequently hybridized to the Affymetrix U133A GeneChip (45°C for 16 hours). Staining, washing and scanning procedures were carried out as described in the GeneChip Expression Analysis Technical Manual (Affymetrix, Santa Clara, CA). All GeneChips were visually inspected for obvious irregularities. The global method of scaling/normalization was applied and the differences between the scaling/normalization factors of all GeneChips (n=294) were less than 3-fold (0.70, SD 0.26). All additional quality metrics, i.e. percent genes present (50.6, SD 3.8), actin 3' to 5' ratio (1.24, SD 0.19) and *GAPDH* 3'to 5' ratio (1.05, SD 0.14) indicated high overall sample and assay quality.

20 *Data normalization, analysis and visualization*

The mean intensity values of all probe sets were calculated by the global method of scaling/normalization using MAS5.0. As most genes with values below 30 are absent (83% of all absent calls), these values were classified as unreliable and set to 30. This process resulted also in the exclusion of possibly unreliable present calls (10% of all present calls). The ratios between measured intensity and geometric mean intensity were calculated for each probe set and log2 transformed to be used for further data analyses with Omniviz®, SAM® and PAM®.

Omniviz® (Maynard, MA (version 3.6)) – Different numbers of probe sets were selected by filtering for those genes that in one or more samples

differed at least n-fold from the geometric mean expression level of all AML patients. By using various ratios different numbers of differentially-expressed probe sets were selected for the correlation visualization tool (Table 2). For each number of selected probe sets the clustering of the AML patients in
5 specific molecularly recognizable groups was investigated using the Correlation Visualization tool of Omniviz (Supplemental Data (Figures B to H)).

Table 5 (below) shows the evaluation of the Correlation View results on the basis of the clustering of AML patients with similar molecular
10 abnormalities.). The few AML cases with abnormalities involving chromosome 5 were excluded. Ratio: ratio between measured intensity and geometric mean intensity by which probe sets were selected.

SAM® (version 1.21) Trustees of Leland Stanford Junior University
- All supervised analyses were performed using Significance Analysis of
15 Microarrays (SAM) (Tusher *et al.*, 2001). The criterion to identify the top40 genes for the assigned clusters was: at least a 2-fold difference between selected cluster and the remaining AML samples and a q-value of less than 5%.

PAM® (version 1.12) Trustees of Leland Stanford Junior University
20 - All supervised class prediction analyses were performed by applying Prediction Analysis of Microarrays (PAM) software in R (version 1.7.1) (Tibshirani *et al.*, 2002).

All genes identified by the SAM and PAM methods are available as
Supplemental Data (Tables A1 to P1 and Q).

25

RT-PCR and sequence analyses

Reverse transcriptase - polymerase chain reactions (RT-PCR) and sequence analyses for mutations in *FLT3*-ITD, *FLT3*-TKD, *N-RAS*, *K-RAS* and *cEBPα*, as well as real-time PCR for *EVII* were performed as described

previously (van Waalwijk van Doorn-Khosrovani *et al.*, 2003a; van Waalwijk van Doorn-Khosrovani *et al.*, 2003b; Valk *et al.*, 2004; Care *et al.*, 2003).

Statistical analyses of survival

5 Statistical analyses were performed with Stata Statistical Software, Release 7.0 (Stata, College Station, TX). Actuarial probabilities of overall survival (OS, with failure death due to any cause) and event-free survival (EFS, with failure in case of no complete remission at day 1, at relapse or death in first CR) were estimated by the method of Kaplan and Meier.

10

Results

Correlation visualization of de novo AML by gene expression

 The best unsupervised ordering by applying the visualization tool of Omniviz of the AML cases in relation to different molecular markers was
15 reached using 2856 probe sets (representing 2008 annotated genes and 146 ESTs) (Figure 1A and Table 5). Sixteen distinct groups of AML patients were assigned on the basis of strong correlation between adjacent AML patients, i.e., within one red square along the diagonal, as well as the correlation and anti-correlation between the different groups, i.e., between the red squares
20 along the diagonal (Figure 1A and Supplemental data (Figure A)). The final Omniviz Correlation View generated with 2856 probe sets was adapted such that cytological, cytogenetic and molecular parameters could be plotted directly adjacent to the original diagonal. This resulted in a unique way of visualization of the groups of patients with high correlation and related
25 parameters (Figure 1B).

 Distinct clusters of AML t(8;21), AML inv(16) and AML t(15;17) were apparent (Figure 1B). Although these distinct clusters were readily identified with less probe sets using the correlation tool, clusters of AML patients with mutations in *FLT3* or *cEBP α* , or with overexpression of *EVII*
30 were only apparent with 2856 probe sets (Table 5 and Figures 4 to 10). When

more genes were used for the correlation visualization this compact clustering vanished (Table 5).

Unique genes characteristic for each of the 16 identified clusters were obtained by supervised analysis using SAM. The expression profiles of the top40 genes are plotted in Figure 1B alongside the Correlation View. The SAM analyses resulted in only 599 discriminating genes (Tables 23-39) since a distinct gene profile for cluster #14 could not be identified, suggesting tight overlap with genes in clusters #7 and #8.

10 *AML and recurrent translocations*

CBFβ/MYH11 - All inv(16) AML patients clustered within cluster #9 (Figure 1B and Supplemental Data (Table I)). Of note, 4 patients who were previously not known to harbour an inv(16) were included within this cluster. Molecular analysis and Southern blotting revealed the presence of

15 *CBFβ/MYH11* fusion gene in those cases (Figure 11). SAM analysis revealed that *MYH11* was the most prominent discriminating gene for this cluster (Supplemental data (Table I1 and Figure 12). Interestingly, *CBFβ* anti-correlated with this cluster, suggesting that the *CBFβ/MYH11* fusion protein down modulates the expression of the *CBFβ* allele.

20 *PML/RARα* - Cluster #12 contains all cases of acute promyelocytic leukemia (APL) with t(15;17) (Figure 1B and Supplemental Data (Table L)), including two patients previously recognized as APL with *PML/RARα* by RT-PCR only. SAM analyses (Supplemental Data (Table L1)) revealed that genes encoding growth factors such as hepatocyte growth factor (*HGF*), macrophage-stimulating 1 (hepatocyte growth factor-like (*MST1*)) and fibroblast growth
25 factor 13 (*FGF13*) were specific for this cluster. In addition, cluster #12 could be separated into two subgroups with either high or low white blood cell count (WBC) (Supplemental data (Figure 13). This subdivision corresponds with *FLT3* ITD mutation status (Figure 1B).

AML1/ETO - All patients with a t(8;21) grouped within cluster #13 (Figure 1B and Supplemental Data (Table M)), including one patient without a t(8;21) (2496). SAM identified ETO as the most discriminative gene for this cluster (Supplemental data (Table M1 and Figure 14)).

5

AML with 11q23 abnormalities

AML patients with 11q23 abnormalities were intermingled within the 286 AML patients, although two subgroups were apparent, i.e., cluster #1 and cluster #16 (Figure 1B and Supplemental Data (Tables A and P)). Cluster #16 contains four cases of t(9;11) and one case of t(11;19) (5/11 cases (45%)). SAM analyses identified a strong signature with a group of genes specifically upregulated in the majority of cases in this cluster (Figure 1B and Supplemental data (Table P1)). Although seven of 14 (50%) cases within cluster #1 have chromosome 11 abnormalities as well, this subgroup appears quite heterogeneous with a less uniform signature (Figure 1B).

15

AML and cEBPα mutations

Interestingly, two separate clusters (#4 and #15) comprise AML patients with predominantly normal karyotypes and a high frequency of mutations in *cEBPα* (Figure 1B (Clusters #4 (8/15 cases (53%)) and #15 (5/8 cases (62%))). In cluster #4 a set of up- and down regulated genes could be defined (Supplemental data (Table D1)), which appeared to discriminate the AML cases in cluster #4 from cluster #15. The upregulated genes represent certain T-cell genes, such as the CD7 antigen (*CD7*) and the T cell receptor delta locus (*TRD@*), which are known to be expressed on immature subsets of AML as well (Lo Coco *et al.*, 1989; Boeckx *et al.*, 2002). All but one of the top40 genes of cluster #15 are downregulated (Supplemental data (Table O1)). Interestingly, these genes are similarly downregulated in cluster #4 (Figure 1B). The genes encoding alpha1-catenin (*CTNNA1*), tubulin beta-5 (*TUBB5*)

25

and Nedd4 family interacting protein 1 (*NDFIP1*) were the only genes down modulated and among the top40 in both cluster #4 and #15.

AML and EVI1 overexpression

5 A separate cluster (#10) of AML was identified in which 44% (10/22 cases, Supplemental data (Table J)) showed increased expression of *EVI1*. Aberrant expression of *EVI1* in cluster #10 correlated with chromosome 7 abnormalities (6/10 *EVI1*-positive cases). This complete group of patients could be discriminated based on a selection of genes, suggesting that all patients, 10 even the *EVI1* negative cases, carry abnormalities in a common pathway. Cluster # 8 also contains a relatively high number of chromosome 7 aberrations (5/13 cases, Supplemental data (Table H)), but it displays a different molecular signature compared to cluster #10 (Figure 1B). This suggests that high expression of *EVI1* and/or *EVI1*-related proteins determines 15 the molecular profile of cluster #10. Four out of 14 cases within the heterogeneous cluster #1 also demonstrated increased *EVI1* expression. These patients may cluster outside cluster #10 since their molecular signatures are most likely the result of *EVI1* overexpression and an 11q23 abnormality.

20 *AML with FLT3 mutations*

Groups of patients with mutations in the *FLT3* receptor gene were recognized within the Correlation View (Figure 1B). In fact, clusters #2 and #6 merely consist of patients with a *FLT3* ITD. Interestingly, almost all of these patients have a normal karyotype. In addition, the *FLT3* ITD mutation status 25 seems to divide several clusters into two groups, e.g., clusters #3, #5 and AML with t(15;17) (#12). Other individual cases of AML with *FLT3* ITD were more dispersed over the whole group of AML patients. AML patients with mutations in the tyrosine kinase domain (TKD) of *FLT3* did not cluster. Likewise patients with mutations in codons 12, 13 or 61 of the small GTPase RAS (N-

RAS and *K-RAS*) do not have apparent signatures and do not aggregate in the Correlation View (Figure 1B).

Other unique AML clusters

5 AML patients with normal karyotypes clustered in several subgroups within the assigned clusters (Figure 1B). In fact, the majority of patients in cluster #11 have normal karyotypes without any consistent additional abnormality. Other unique clusters, i.e., cluster #3, #5, #7, #8 and #14, were identified which could not be annotated with any known cytogenetic
10 or molecular abnormality. Cluster #5 mainly contains AML patients that belong to the French-American-British (FAB) classification M4 or M5 subtypes (Figure 1B), suggesting that the morphology was the main determinant for classifying these cases within this subgroup. Clusters #3, #7, #8, #11 and #14 contain AML cases, that do not belong to one FAB subtype, but can be
15 discriminated based on distinct gene expression profiles.

Class prediction of distinct clusters in AML

 All 286 AML cases were randomised and divided into a training- (n=190) and a validation set (n=96). PAM was applied on the dataset to
20 determine the minimal number of genes to predict distinct abnormalities with prognostic value in AML¹, i.e., t(8;21), inv(16), t(15;17), 11q23 (cluster #16), *EVII*/monosomy 7 (cluster #10), *cEBPα* (clusters #4 and #15) (Table 3). In addition, since *FLT3* ITD mutations are frequent abnormalities in AML and associated with poor outcome², the minimal set of genes to predict *FLT3* ITD
25 mutations in AML were identified.

 All patients with favourable cytogenetics within the validation set were predicted with 100% accuracy and with only few genes (Table 3). As expected from the SAM analyses, *ETO* for t(8;21), *MYH11* for inv(16) and *HGF* for t(15;17) were among the most predictive genes (Supplemental Data (Table
30 Q)). Interestingly, cluster #10 (*EVII*/ monosomy 7) was predicted with high

accuracy, although with a higher 10-fold cross validation error. Cluster #16 (11q23) was predicted with fairly high accuracy. Since cluster #15 (cEBP α) consists of few patients only, we combined both cEBP α clusters. These two clusters could subsequently be predicted within the validation set with fairly high accuracy. A highly predictive signature for the *FLT3* ITD cluster could not be defined by means of expression profiling within the AML patient cohort investigated.

Table 3 (below) shows the class prediction using PAM (10-fold CV error: 10-fold cross validation prediction error on training set (n=190), Error validation set: prediction error on validation set (n=96), #Probe sets: Number of probe sets used for prediction, #Genes: number of genes represented by probe sets used for prediction. For identities of the probe sets and genes see Supplemental Data (Table Q). *After randomization none of the AML patients from cEBP α cluster #15 were included in the validation set.

15

Survival analyses

Overall survival (OS), event free survival (EFS) and relapse rate (RR) of AML patients from clusters containing >20 cases in the Correlation View, were determined, i.e., clusters #5 (M4/M5), #9 (inv(16)), #10 (*EVII*/monosomy 7), #12 (t(15;17)) and #13 (t(8;21)). Patients with a complete clinical data set were included in the survival analyses (Figure 2). The mean actuarial OS and DFS probabilities at 60 months of the patients with favourable cytogenetics were 62% ($\pm 8.7\%$) and 50% ($\pm 2.4\%$), respectively. AML patients included in cluster #5 had intermediate survival (OS 27% and EFS 32%), whereas patients from cluster #10 showed poor treatment response (OS 6% (P=0.001) and EFS 18% (P=0.004)) mainly as a result of increased relapse incidence (Figure 2C).

25

Discussion

30

The results of the study presented here show profound diagnostic

impact of expression profiling. Among AML with considerable genetic diversity, expression profiling provides an approach to distinguish these highly variable genetic subsets into clusters with distinct signatures. Patients with AML were classified in 16 groups based on their gene expression profiles by
5 unsupervised Pearson's correlation coefficient analyses. The results show that each of the assigned clusters represents true AML subgroups with specific molecular signatures.

Firstly, all cases with t(8;21) (*AML1/ETO*), inv(16) (*CBF β /MYH11*) or t(15;17) (*PML/RAR α*), including patients that could not be recognized by
10 karyotyping, could be clustered in three separate clusters with unique gene expression profiles. Unique correlations between gene expression profiles and favourable cytogenetic aberrations have been shown in the prior art (Debernardi *et al.*, 2003; Schoch *et al.*, 2002), however, here we demonstrate that these patients can even be recognized with high accuracy within a
15 representative cohort of AML patients.

Secondly, Significance Analyses of Microarrays (SAM) and Prediction Analyses of Microarrays (PAM), showed a strong concordance between the specific genes identified for the different assigned clusters, demonstrating that we identified truly discriminative genes for all the clusters
20 that we assigned. For instance, we identified two distinct clusters (#4 and #15) with overlapping signatures, which both included cases with normal karyotypes and mutations in *cEBP α* . Multiple genes appeared to be downregulated in both subclasses but were unaffected in any other AML subgroup.

25 Thirdly, the discriminative genes identified by SAM and PAM may in addition reveal specific functional pathways critical for the pathophysiology of AML. This is suggested by the identification of several functionally important genes implicated in specific subtypes of AML, such as the IL5R α in AML with t(8;21) (Touw *et al.*, 1991) and the bona fide FLT3/STAT5 targets
30 IL2R α (Kim *et al.*, 2001) and *PIM1* (Lilly *et al.*, 1992) in AML with *FLT3* ITD

mutations.

Five clusters (#5, #9, #10, #12 and #13) 20 or more cases were evaluated in relation to outcome of therapy. As expected, clusters #9 (*CBF β /MYH11*), #12 (*PML/RAR α*) and #13 (*AML1/ETO*), comprised cases with a favorable response to therapy. However, cases that belong to cluster #10 showed a distinct poor outcome. Patients in this cluster could be predicted with high accuracy in an independent validation set with a minimal set of genes. The high frequency of poor prognostic markers, e.g., -7(q), -5(q), t(9;22) or high *EVII* is in agreement with the observation that this cluster represents a bad-risk AML group. However, since the cluster contains AML cases with a variety of genetically defined poor risk markers and since a significant portion of the cases did not express any of these lesions, this suggests that a unique pathway represented by the molecular signature of this cluster of AML patients is associated with bad outcome.

This hypothesis is further strengthened by the fact that large numbers of cases with the same poor-risk markers were present in other clusters (#1, #2, #8 and #16). Analysis of the genes up- or downregulated in AML cases from cluster #10 may predict the pathway(s) involved the pathophysiology of this subgroup of AML patients. This might also shed light on the findings that the other cases with distinct poor-prognostic markers are grouped in different clusters. Unfortunately, these latter groups were too small for an accurate analysis of treatment outcome.

The 44 AML patients in cluster #5 showed an intermediate survival estimate. Since these cases belong to AML FAB-M4 or -M5 subtype, it is possible that monocyte/macrophage related genes mainly drove clustering of these cases. Unsupervised clustering of larger numbers of only AML FAB-M4 or -M5 cases with a normal karyotype may result in the identification of specific subgroups with unique gene expression profiles and perhaps variable prognosis.

Three clusters mainly consisting of patients with normal karyotype

were identified. The majority of patients in two of those clusters (#2 and #6) were also characterized by *FLT3* ITD mutations, whereas patients in cluster #11, with a discriminative molecular signature, did not contain any consistent abnormality.

5 Two clusters (#1 and #16) were recognized, which harbored 11q23 abnormalities, representing defects involving the mixed-lineage leukemia gene. The reason for the separation of these two subgroups is most likely caused by different additional genetic defects in the cases of the distinct clusters, causing different gene expression profiles. In cluster #1 this
10 abnormality may be the frequently observed high expression of *EVII*, which is not apparent in AML cases from cluster #16. A similar explanation may hold for AML cases in clusters #4 and # 15, both comprising *cEBP α* mutant cases, AML patients in clusters #1 and #10 (high *EVII* expression), or patients in clusters # 8 and #10 with frequent monosomy 7. Given the fact that each of
15 these clusters expressed such a distinct molecular signature most probably means that in the cases without the characteristic genetic lesion, other currently unidentified mutations affecting the same pathways are responsible for the genetic profiles.

 Internal tandem duplications (ITD) in the *FLT3* gene adversely
20 affect clinical outcome (Levis & Small, 2003). The molecular signature induced by the constitutively activated the FLT3 receptor appears not strong enough to distinguish *FLT3* ITD carrying AML patients from the other cases. However, the clustering of *FLT3* ITD positive patients within assigned clusters, as is the case in the APL subgroup (cluster #12), demonstrates that the presence of
25 *FLT3* ITD results in different biological entities within one type of disease.

 To this end, our study demonstrates that cytogenetically known as well as new clusters of AML with characteristic gene expression signatures can be identified with one single assay. The quality of genome-wide analysis will further advance with the availability of novel whole genome arrays,
30 improved sequence annotation and the development of more sophisticated

protocols and software, allowing analysis of subtle differences in gene expression and comprehensive pathway prediction. These studies, while augmenting our understanding of the pathways involved in pathophysiology of AML, will result in improved diagnostics and possibly lead the way to the development anti-cancer drugs that interfere with disease related pathways.

EXAMPLE 2

Analyses of novel AML patients

10 Patients and cell samples

Eligible patients have a diagnosis of primary AML, confirmed by cytological examination of blood and bone marrow. Blasts and mononuclear cells should be purified by Ficoll-Hypaque (Nygaard, Oslo, Norway) centrifugation. Add 1:1 diluted peripheral blood or bone marrow 1:4 diluted both in PBS up to 20-25 ml on to 15 ml Ficoll-Hypaque. Spin 15 minutes at 1880rpm. Collect interphase with mononuclear cells and wash twice with PBS (total volume 50ml, 8 minutes 2000 rpm). The pellet contains the mononuclear cells, including the blast cells. As a result, the AML samples should contain 80-100 percent blast cells, regardless of the blast count at diagnosis. $30 \cdot 10^6$ cells/ml should be frozen in 1vol PBS/1 vol heat inactivated FCS/0.5 vol DMSO stored in liquid nitrogen.

RNA isolation and quality control

After thawing, cells were washed once with Hanks balanced salt solution. High quality total RNA should extracted by lysis with guanidinium isothiocyanate followed by cesium chloride gradient purification. RNA concentration, quality and purity should be examined using the RNA 6000 Nano assay on the Agilent 2100 Bioanalyzer (Agilent, Amstelveen, The Netherlands). None of the samples should show RNA degradation (28S/18S rRNA ratio ≥ 2) or contamination by DNA.

Gene profiling and quality control

Ten µg of total RNA should be used to prepare antisense biotinylated RNA. Single-stranded cDNA and double-stranded cDNA should be synthesized according to the manufacturer's protocol (Invitrogen Life Technologies, Breda, The Netherlands) using the T7-(dT)24-primer (Genset Corp, Paris, France). *In vitro* transcription should be performed with biotin-11-CTP and biotin-16-UTP (Perkin Elmer, Hoofddorp, The Netherlands) and the MEGAScript T7 labeling kit (Ambion, Cambridgeshire, UK). Double-stranded cDNA and cRNA should be purified and fragmented with the GeneChip® Sample Cleanup Module (Affymetrix, Santa Clara, CA). Biotinylated RNA should be hybridized to the Affymetrix U133A GeneChip® (45°C for 16 hours). Samples should be analyzed using Affymetrix U133A or U133 Plus2.0 GeneChips®. The U133A GeneChip® contains 22283 probe sets, representing approximately 13000 genes. These probe sets can also be selected from the U133 Plus2.0 GeneChip®. Staining, washing and scanning procedures should be carried out as described in the GeneChip® Expression Analysis Technical Manual (Affymetrix, Santa Clara, CA). All GeneChips® should be visually inspected for irregularities. The global method of scaling/normalization should be applied and the differences between the scaling/normalization factors of all GeneChips® up to the Target Gene Intensity of 100 (reference value n=285: scaling factor = 0.70, SD 0.26). All additional measures of quality - percent genes present (reference value n=285: 50.6 ±3.8), actin 3' to 5' ratio (reference value n=285: 1.24 ±0.19) and *GAPDH* 3'to 5' ratio (reference value n=285: 1.05 ±0.14) - should indicate high overall sample and assay quality.

Reference data set

A reference data set (gene expression data and detailed clinical and molecular data) of 285 AML patients should be downloaded from the Gene Expression Omnibus (www.ncbi.nlm.nih.gov/geo, accession number GSE1159).

Data normalization, analysis and visualization

All intensity values (reference set (n=285) and new AML patients to be included) should be scaled to an average value of 100 per GeneChip®

- 5 according to the method of global scaling/normalization, available in the Affymetrix Microarray Suite (MAS5.0). All other setting should be default according to the manufacturer.

- As our methods reliably identify samples with an average intensity value >30 but do not reliably discriminate values from 0 - <30, these values should be set
10 to 30.

- For each probe set the geometric mean of the hybridization intensities of all patient samples should be calculated. The level of expression of each probe set in every sample was determined relative to this geometric mean and transformed to log₂ to ascribe equal weight to gene-expression levels with similar relative
15 distances to the geometric mean. The transformed expression data should be subsequently imported into Omniviz.

- Pearson's Correlation Visualization tool of Omniviz* (Maynard, MA (version 3.6)) – The Omniviz package should be used to perform and visualize
20 unsupervised cluster analysis. The clustering of molecularly recognizable specific groups of patients should be investigated with the 2856 probe sets (Table 1) taking the reference set (n=285) and new patients to be analysed into account.

Claims

1. A method for producing a classification scheme for AML comprising the steps of:
 - a) providing a plurality of reference samples, said reference samples comprising cell samples from a plurality of reference subjects affected by AML;
 - b) providing reference profiles by establishing a gene expression profile for each of said reference samples individually;
 - c) clustering said individual reference profiles according to a statistical procedure, comprising:
 - (i) K-means clustering;
 - (ii) hierarchical clustering; and
 - (iii) Pearson correlation coefficient analysis; and
 - d) assigning an AML class to each cluster.
2. Method according to claim 1, wherein the clustering of said gene expression profiles is performed based on the information of differentially-expressed genes.
3. Method according to claim 1 or 2, wherein the clustering of said gene expression profiles is performed based on the information of the genes of Table 1, more preferably of Table 2.
4. A method for classifying the AML of an AML affected subject, comprising the steps of:
 - a) providing a classification scheme for AML by producing such a scheme according to the method of any one of claims 1-3;

- b) providing a subject profile by establishing a gene expression profile for said subject;
- c) clustering the subject profile together with reference profiles;
- d) determining in said scheme the clustered position of said subject profile among the reference profiles, and
- 5 e) assigning to said AML of said subject the AML class that corresponds to said clustered position in case said subject profile is within any cluster of reference profiles, or assigning to said AML of said subject a new AML class.
- 10
5. A method for diagnosing AML in a subject comprising the steps of:
- a) producing a classification scheme for AML according to the method of any one of claims 1-3;
- b) defining cluster-specific genes for each cluster by selecting those genes of which the expression level characterizes the clustered position of the
- 15 corresponding AML class among the various AML classes within said scheme;
- c) determining the level of expression of one or more of said cluster-specific genes in a subject;
- 20 d) establishing whether the level of expression of said cluster-specific genes in said subject shares sufficient similarity to the level of expression that characterizes an individual AML class to thereby determine the presence of AML corresponding to said class in said subject.
- 25 6. Method according to claim 5, wherein said cluster-specific genes comprise a set of 1 to 3000 genes of the genes of table 1, more preferably 1 to 600 genes of the genes of table 1, still more preferably 1 to 50 genes of the genes of table 1.

7. Method according to claim 5, wherein said cluster-specific genes comprise a set of 1 to 600 genes of the genes of table 2, still more preferably 1 to 50 genes of the genes of table 2, and even more preferably 1 to 25 genes of the genes of table 2.

5

8. Method according to claim 5, wherein said cluster-specific genes are selected from the genes of Table 3.

9. A method of determining the prognosis for an AML affected subject, said method comprising the steps of:

- 10 a) providing a classification scheme for AML by producing such a scheme according to the method of any one of claims 1-3;
- b) determining the prognosis for each AML class in said scheme based on clinical records for the AML subjects comprised in said class;
- 15 c) establishing the AML class of an AML affected subject by diagnosing AML in said subject according to any one of the methods 5-8 or by classifying the AML in said subject according to a method of claim 4, and
- d) assigning to said subject the prognosis corresponding to the established
- 20 AML class of said AML affected subject.

10. A method of determining the prognosis for an AML affected subject, said method comprising the steps of:

- a) isolation of RNA from mononuclear cells of said subject;
- 25 b) preparation of antisense, biotinylated RNA to the RNA of step a);
- c) hybridisation of said antisense, biotinylated DNA on Affymetrix U133A or U133 Plus2.0 GeneChips®;
- d) normalising the measured values for the gene set of Table 1;
- e) clustering the obtained data together with the reference data, obtainable
- 30 from (www.ncbi.nlm.nih.gov/geo, accession number GSE11159); and

f) determining the prognosis on basis of the subgroup/cluster to which the data of the subject are clustering.

11. Classification scheme for AML, said scheme comprising a plurality
5 of distinct AML classes that are differentiated on the basis of similarity
clustering of gene expression profiles obtained from a plurality of reference
subjects affected by AML.
12. A method of detecting an AML-associated transcript in a cell from a
10 patient, the method comprising contacting a biological sample from the patient
with a polynucleotide that selectively hybridizes to a sequence at least 80%,
preferably at least 95% identical to a sequence as shown in Table 1, 2 or 3.
13. Method according to claim 12, wherein said polynucleotide
15 selectively hybridizes to a sequence at least 95% identical to a sequence as
shown in Table 1, 2 or 3.
14. Method according to claim 12, wherein said polynucleotide
comprises a sequence as shown in Tables 1 or 2.
20
15. Method according to any one of claims 12-14, wherein said biological
sample is a tissue sample.
16. Method according to any one of claims 12-15, wherein the biological
25 sample comprises isolated nucleic acids, e.g., mRNA.
17. Method according to any one of claims 12-16, wherein the
polynucleotide is labeled, e.g., with a fluorescent label.

18. Method according to any one of claims 12-17, wherein the polynucleotide is immobilized on a solid surface.
19. Oligonucleotide probe capable of hybridizing under stringent
5 conditions to one or more of the AML-associated genes selected from Table 1, preferably to one or more of the genes selected from Table 2, more preferably to one or more of the genes selected from Table 3.
20. Oligonucleotide microarray comprising at least 1, preferably at least
10 2, more preferably at least 25, still more preferably at least 100 oligonucleotide probes according to claim 19.
21. Kit-of-parts comprising an oligonucleotide microarray according to
claim 20 and means for comparing a gene expression profile determined by
15 using said microarray with a database of AML reference expression profiles.
